

Two notebooks are available in the archive:

- ExploratoryDataAnalysis can (does not have to) be run first. It contains code that will create a dataset for both analysis and training (if such dataset has not been previously created)
- Model can be run either before or after the ExploratoryDataAnalysis as it also contains the code for dataset generation.

Additionally, several folders are available:

- data - contains the raw data. It is also the default destination for saving the dataset for model/EDA and the training/test subsets
- docker - contains all the files necessary for Docker container creation with LightGBM package inside.
- processing - contains all the helper functions that are used to process the dataset for model/EDA
- skscripts - contains training scripts for scikit learn linear regression and random forests
